# Statistical models

- Events of interest defined in terms of random quantities  $x_1, \ldots, x_n$
- Individual's degrees of belief specified as a joint distribution function P(x<sub>1</sub>,..., x<sub>n</sub>) (or density p(x<sub>1</sub>,..., x<sub>n</sub>))
- In an application a specific form for *p* is chosen
- Here we study more general belief structures that lead to a mathematical representation of a model

- Sometimes the indices of the random quantities x<sub>1</sub>,..., x<sub>n</sub> are judged not to be significant
- This leads to the notion of finite exchangeability

#### Definition (Finite exchangeability)

The random quantities  $x_1, \ldots, x_n$  are finitely exchangeable under a probability measure *P* if

$$P(x_1,\ldots,x_n)=P(x_{\pi(1)},\ldots,x_{\pi(n)})$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○○

for all permutations  $\pi$ .

### • Partial and infinite exchangeability

(日) (日) (日) (日) (日) (日) (日)

## The Bernoulli model

Infinite exchangeability for 0-1 random quantities
⇒ the Bernoulli model

Theorem (Representation theorem for 0-1 random quantities)

If  $x_1, x_2, ...$  are 0-1 random quantities and infinitely exchangeable under P, their joint mass function p is of the form

$$p(x_1,\ldots,x_n)=\int_0^1\prod_{i=1}^n\theta^{x_i}(1-\theta)^{1-x_i}dQ(\theta),$$

where  $Q(\theta) = \lim_{n\to\infty} P(y_n/n \le \theta)$  with  $y_n = x_1 + \cdots + x_n$ .

# The multinomial model

Infinite exchangeability for 0-1 random vectors
the multinomial model

#### Theorem

If  $\mathbf{x}_1, \mathbf{x}_2, \ldots$  are 0-1 random vectors and infinitely exchangeable under P, their joint mass function p is of the form

$$p(\mathbf{x}_1,\ldots,\mathbf{x}_n) = \int_{\Theta} \prod_{i=1}^n \theta_1^{\mathbf{x}_{i1}} \ldots \theta_k^{\mathbf{x}_{ik}} \left(1 - \sum_{j=1}^k \theta_j\right)^{1 - \sum_j \mathbf{x}_{ij}} dQ(\boldsymbol{\theta}),$$

where  $Q(\theta) = \lim_{n\to\infty} P((\bar{x}_{1n} \le \theta_1) \cup \cdots \cup (\bar{x}_{kn} \le \theta_k))$ , with  $\bar{x}_{in} = n^{-1}(x_{1i} + \cdots + x_{ni})$ .

## The general model

Infinite exchangeability for real-valued random quantities
something rather abstract:

#### Theorem

If  $x_1, x_2, ...$  are real-valued infinitely exchangeable random quantities under probability measure *P*, the form of *P* is

$$P(x_1,\ldots,x_n)=\int_{\mathcal{F}}\prod_{i=1}^n F(x_i)dQ(F)\,,$$

where  $Q(F) = \lim_{n\to\infty} P(F_n)$ ,  $F_n$  being the empirical distribution defined by  $x_1, \ldots, x_n$ .

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○○

## Spherical symmetry

- The general representation theorem does not provide a concrete usable model
- More assumptions needed in addition to infinite exchangeability

#### Definition (Spherical symmetry)

A random vector  $\mathbf{x} = [x_1, ..., x_n]$  has spherical symmetry under *P*, if  $P(\mathbf{x}) = P(\mathbf{Ax})$  for all orthogonal matrices **A**.

## The normal model

• Spherical symmetry  $\implies$  the normal model

### Theorem (Representation theorem under spherical symmetry)

If  $x_1, x_2, ...$  is an infinite sequence of real-valued random quantities with probability measure P, and if, for any n,  $\mathbf{x}_n := [x_1, ..., x_n]$  has spherical symmetry, the distribution of  $\mathbf{x}_n$  has the form

$$P(\mathbf{x}_n) = \int_0^\infty \prod_{i=1}^n \Phi(\lambda^{1/2} x_i) dQ(\lambda),$$

where  $\Phi$  is the standard normal distribution function and  $Q(\lambda) = \lim_{n \to \infty} P(s_n^{-2} \le \lambda)$  with  $s_n^2 := n^{-1}(x_1^2 + \dots + x_n^2)$ .

# Origin invariance

- Exchangeability of positive random quantities ⇒ symmetry of events w.r.t. the 45° line through the origin
- Extension of this:

### Definition (Origin invariance)

An infinitely exchangeable sequence  $x_1, x_2, ...$  of positive real-valued random quantities with probability measure *P* has origin invariance if for all *n* and any event  $A \subset \mathbb{R}^n_+$ 

$$P((x_1,\ldots,x_n)\in A)=P((x_1,\ldots,x_n)\in A+a)$$

for all  $\mathbf{a} \in \mathbb{R}^n$  such that  $\mathbf{a}^T \mathbf{1} = 0$ .

### The exponential model

### • Origin invariance $\implies$ the exponential model

#### Theorem (Continuous representation under origin invariance)

If the sequence  $x_1, x_2, \ldots$  of positive real-valued random quantities has origin invariance under P, the joint density has the form

$$p(x_1,\ldots,x_n) = \int_0^\infty \prod_{i=1}^n \theta \exp(-\theta x_i) dQ(\theta),$$

where  $Q(\theta) = \lim_{n \to \infty} P(\bar{x}_n^{-1} \leq \theta)$  with  $\bar{x}_n = n^{-1}(x_1 + \cdots + x_n)$ .

### Exercise

Come up or find in literature a model for a sequence of real-valued random variables  $x_1, x_2, \ldots$  that is infinitely exchangeable and whose representation in terms of the general representation theorem genuinely involves an integral over measures. Write down the model using the notation of Proposition 4.3.
